Intermediate-high-risk pulmonary embolism: redefining it better with the support of the pulmonary embolism response teams approach

Tromboembolia pulmonar aguda de riesgo intermedio-alto: redefiniéndose mejor con el apoyo de los equipos de respuesta rápida en tromboembolia pulmonar

Pulmonary embolism (PE) represents the third most common cause of cardiovascular death in western countries after acute coronary syndromes and stroke¹⁻³. Recently, the 2014 European Society of Cardiology (ESC) guidelines further subdivided intermediate-risk PE into two subgroups: intermediate-low- and intermediate-high-risk PE, the latter, may portend worse prognosis with an estimated 30-day mortality ranging from 5% to 25%².

The current clinical trials focusing in reperfusion therapeutic strategies are still using their own arbitrary definition of the intermediate-risk (submassive) PE across studies (e.g., PEITHO, MOPETT, ULTIMA, and SEATTLE-II trials) perhaps, either underestimating or overestimating the disease. As previously emphasized and accurately pointed out by the ESC guidelines, not all the intermediate-risk patients are built the same or “fits all,” do not have similar risk profile nor prognostic outcomes. Thus, we would like to propose a practical multimodality based, uniform, and homogeneous novel definition of intermediate-high-risk PE.

Redefining intermediate-high-risk PE

The redefinition of intermediate-high-risk PE encompasses a series of clinical findings (e.g., clinical severity

scores that include tachycardia, tachypnea, hypoxemia, concomitant proximal deep vein thrombosis, previous comorbidities such as chronic pulmonary disease or heart failure, and high index for rapid clinical deterioration); electrocardiographic findings (e.g., new complete or incomplete right bundle branch block, and antero-septal ST depression or elevation); echocardiographic and computed tomographic angiographic parameters (e.g., objective qualitative and quantitative signs of the right ventricular dysfunction); as well as the elevation of biomarkers suggesting myocardial injury (e.g., brain natriuretic peptide and troponin elevation)^{3,4}. Table 1 integrates all the key aspects for such proposed novel definition of intermediate-high-risk PE.

Pulmonary embolism response teams (PERT)

We believe that through the implementation, adoption, and appropriate use of a designated hospital-based PERT, more rapid detection, risk stratification, formulation of a therapeutic strategy, and mobilization of specific resources (e.g., catheterization suite or the operating room for emergent pulmonary embolectomy) can be achieved for a given complex case of PE, and within

Table 1. Proposal of important key points for a uniform, homogeneous, and standardized definition for intermediate-high-risk pulmonary embolism for further clinical trials and collection of data in research

— Integrated multimodality clinical risk stratification that includes clinical judgment, high index of suspicion for rapid deterioration (e.g., shock index, tachycardia, hypoxemia, and concomitant proximal deep vein thrombosis), severity grading scores such as the PESI > 106 points or the sPESI score > 1 points.
— Objective evidence of RV dysfunction by echocardiographic or CTA criteria that include the following: Quantitative and qualitative echocardiographic findings such as RV/LV end-diastolic ratio > 1 (seen at four-apical long-axis chamber views) or by CTA > 0.9, RV end-diastolic diameter > 33 mm, pulmonary arterial systolic pressure estimated > 30 mmHg, or tricuspid regurgitant jet velocity > 2.8 m/s.
— Significant electrocardiographic changes such as new complete or incomplete right bundle branch block, ST-segment depression, and/or significant T waves inversions in anteroseptal leads (V1-V4).
— Significant elevation of the biomarkers of myocardial injury: BNP > 100 pg/ml or N-terminal pro-BNP > 500 pg/ml; troponin I > 0.4 ng/ml, or troponin T > 0.1 ng/ml.
— SI > 1 (SI = HR/SBP) despite SBP > 90 mmHg (e.g., HR of 128 bpm and SBP 105 mmHg), thus, predicting early clinical deterioration or hemodynamic collapse during the next 24-48 h, requiring rescue reperfusion strategies (e.g., systemic thrombolysis or catheter-directed therapies).

PESI: pulmonary embolism severity index; sPESI: simplified PESI; RV: right ventricular; CTA: computed tomographic angiography; BNP: Brain natriuretic peptide; SI: shock index; HR: heart rate; SBP: systolic blood pressure

90 min after the activation or consultation of a PERT, formulated the best therapeutic modality by unanimous decision⁵. PERT leverages the exposure and expertise from various subspecialties across medicine while taking care of the most challenging and complex cases of PE. These teams must require from the talent, experience, motivation, and close collaboration from multiple medical and surgical specialties such as emergency medicine physicians, acute hospitalists, intensivists/pulmonologists, interventional cardiologists and radiologists, cardiothoracic surgeons, vascular medicine, and hematologists with a focus in the evolving field of thrombosis⁵.

The first PERT was created in 2012 at the Massachusetts General Hospital in Boston. Since then, > 80 health-care institutions across the USA have adopted their PERT model⁶. The rationale and modus operandi from the PERT are based on the code heart and rapid response teams⁷. PERT facilitates expert knowledge exchange and skills among the multidisciplinary members, generating a consensus opinion to assess specific risks versus benefits for a certain therapeutic modality or intervention, especially in which lack of evidence-based medicine or clinical data exists⁵⁻⁷.

PERT members must be clinicians with a strong motivation, mutual interest, dedication, and full commitment to the care of PE, since these elements are keyed for the success of a given PERT.

We strongly believe that with the setup, initiation and worldwide dissemination of PERT will create the following benefits:

1. Provide fast, efficient, organized, individualized, and best evidence-based care in complex case of PE.
2. Provide collection and interpretation of database, thus, generating updated medical literature with publications in regards best care in PE.
3. Generate and perform high-quality care core measures in acute cardiovascular and pulmonary care.
4. Coordinate patient care with great collaborative team effort across multiple specialties, leveraging them to bring their experience and special skills and knowledge all together.
5. Further areas of clinical research in the field of venous thromboembolism.
6. A vehicle and dissemination of education not only to our physicians but also to our patients.
7. Represent soon, a shifting paradigm and new standard of care in the world of acute PE.

PERT represents a novel process, approach, and strategy, which had emerged to advance, individualized in a case-by-case basis, and personalized therapeutic modalities, especially for intermediate-high and high-risk PE patients, positively impacting quality of life and survival.
